

Introduction to Dimensionality Reduction

Some recent approaches in statistics and machine learning

Julien Chiquet

UMR MIA Paris-Saclay, AgroParisTech, INRAE

May 25, 2023

<https://jchiquet.github.io/>

Outline

- 1 Introduction
- 2 Background: Geometric view of PCA
- 3 Reconstruction error approach
- 4 Generative models
- 5 Preserving pairwise relations
- 6 Probabilistic Neighborhood Embedding

Exploratory analysis of (modern) data sets

Assume a table with n individuals described by p features/variables

$$\mathbf{X}_{n \times p} = \begin{array}{|c|c|c|c|c|} \hline & & & & \\ \hline & & & & \\ \hline & & x_{ij} & & \\ \hline & & & & \\ \hline & & & & \\ \hline \end{array}$$

- genetics: variant j in genome i
- genomics: gene j in cell i
- ecology: species j in site i
- image: pixel j in image i
- etc.

Questions

Look for **patterns** or **structures** to summarize the data by

Challenges

- **Large** (n and p grows) and **high dimensional** (n grows but $\ll p$)
- **Redundancy** many variables may carry the same information
- **Unsupervised**: we don't (necessary) know what we are looking for
- **Discrete**: measures with counts are as common as with intensity

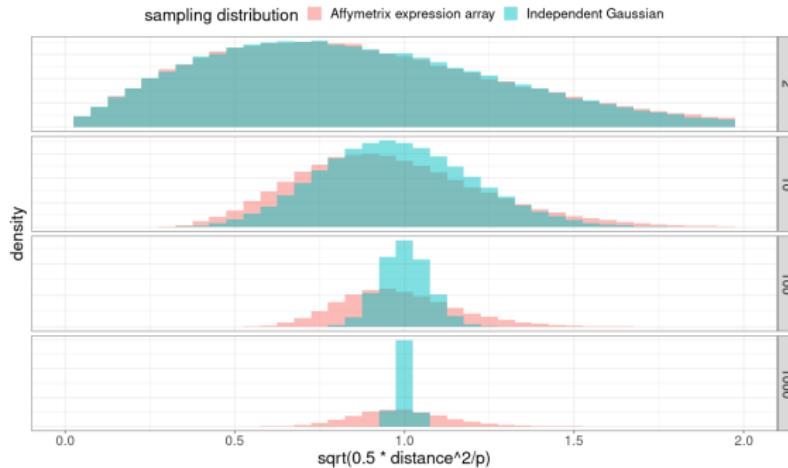

Dimensionality curse

Theorem (Folks theorem)

Let $\mathbf{x}_1, \dots, \mathbf{x}_n$ be in the p -hypercube with i.i.d. coordinates. Then,

$$p^{-1/2} (\max \|\mathbf{x}_i - \mathbf{x}_{i'}\|_2 - \min \|\mathbf{x}_i - \mathbf{x}_{i'}\|_2) = 0 + \mathcal{O}\left(\sqrt{\frac{\log n}{p}}\right)$$

When p is large, all the points are almost equidistant

Hopefully, the data are not really leaving in p dimensions!

Dimension reduction: general goals

Main objective: find a **low-dimensional representation** that captures the “essence” of (high-dimensional) data

Application in Machine Learning

Preprocessing, Regularization

- Compression, denoising, anomaly detection
- Reduce overfitting in supervised learning

Application in Statistics/Data analysis

Better understanding of the data

- descriptive/exploratory methods
- visualization (difficult to plot and interpret $> 3d!$)

See Chapter 20 in Murphy (2022) for a nice, recent introduction and Chapter 14 in Hastie et al. (2009) for reference.

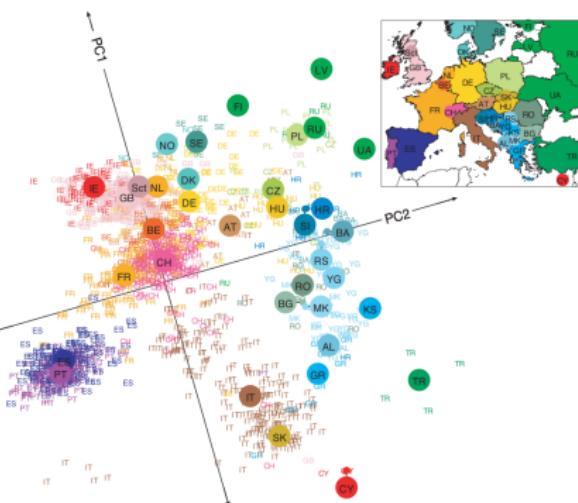

Example in genetics

Genetics variant in European population

500,000 variants (Single Nucleotide Polymorphism) for 3000 individuals

- SNP: 90 % of human genetic variations
 - coded as 0, 1 or 2 (# alleles different against pop. reference)

Summarized with 2 features¹

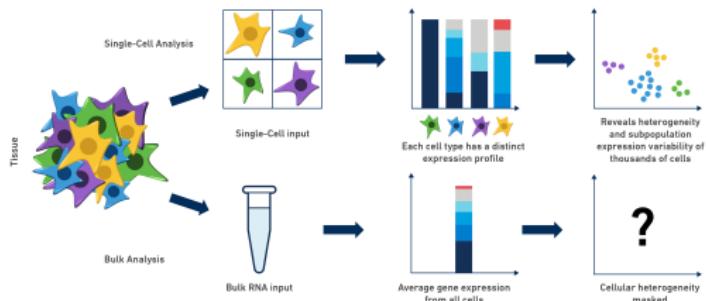

- an extremely strong structure between individuals
("clustering")
 - a very simple subspace where it is obvious
("dimension reduction")

¹source: Nature “Gene Mirror Geography Within Europe”, 2008

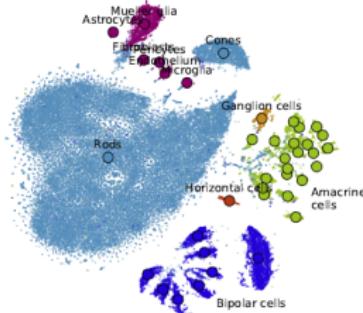

Example in genomics

Genome-wide cell biology with single-cell RNAseq data

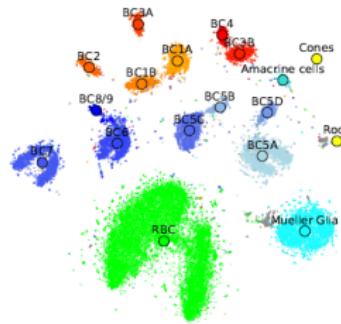

Describe cell population ($n \rightarrow 10^6$) with high dimensional molecular features ($p \rightarrow 10^5$)

Dimension reduction: problem setup

Dimension Reduction Map

- Original data : $\{\mathbf{x}_1, \dots, \mathbf{x}_n\} \in \mathbb{R}^p$
- Low dimensional data : $\{\mathbf{z}_1, \dots, \mathbf{z}_n\} \in \mathbb{R}^q, q \ll p$
- Space \mathbb{R}^p of possibly high dimension: $n \ll p$

Construct a map Φ from \mathbb{R}^p into a \mathbb{R}^q with $q \ll p$:

$$\Phi : \begin{cases} \mathbb{R}^p \rightarrow \mathbb{R}^q, q \ll p \\ \mathbf{x} \mapsto \Phi(\mathbf{x}) \triangleq \mathbf{z} \end{cases}$$

⤱ How should we design/construct Φ ?

Criterion

- Geometrical approach
- Reconstruction error
- Relationship preservation

Form of the map Φ

- Linear or non-linear?
- interpretability and versatility?
- high or low computational resource?

Outline

Cloud of observation in \mathbb{R}^p and Inertia

Individuals in the variable space \mathbb{R}^p

Cloud \mathbf{X} is centered around^a $\bar{\mathbf{x}} = \sum_{i=1}^n \mathbf{x}_i / n$

$$\mathbf{X}^c = \begin{pmatrix} x_{11} - \bar{x}_1 & \dots & x_{1j} - \bar{x}_j & \dots & x_{1p} - \bar{x}_p \\ \vdots & & \vdots & & \vdots \\ x_{i1} - \bar{x}_1 & \dots & x_{ij} - \bar{x}_j & \dots & x_{ip} - \bar{x}_p \\ \vdots & & \vdots & & \vdots \\ x_{n1} - \bar{x}_1 & \dots & x_{nj} - \bar{x}_j & \dots & x_{np} - \bar{x}_p \end{pmatrix}$$

^aempirical mean, barycentrum, center of inertia

Figure 3: Example in \mathbb{R}^3

Total Inertia I_T as a measure of information

Distances to the center of the cloud \propto the total empirical variance

$$I_T = \frac{1}{n} \sum_{i=1}^n \sum_{j=1}^p (x_{ij} - \bar{x}_j)^2 = \frac{1}{n} \sum_{i=1}^n \text{dist}^2(\mathbf{x}_i, \bar{\mathbf{x}}) = \sum_{j=1}^p \mathbb{V}(\mathbf{x}^j) = \text{trace}(\hat{\Sigma})$$

⇒ Good representation has large inertia (much variability)

Geometric view in a nutshell

Consider collection of orthogonal axes (with dimension =1), then

$$I_T = I_{\Delta_1} + I_{\Delta_2} + \cdots + I_{\Delta_p}$$

PCA is matrix factorisation (Hotelling 1933)

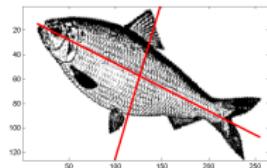

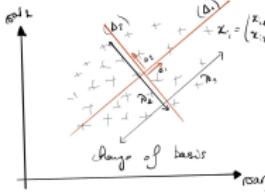

$$\hat{\Sigma} = \mathbf{V}\Lambda\mathbf{V}^T, \quad \mathbf{V} = (\mathbf{v}_1 \quad \mathbf{v}_2, \quad \dots \quad \mathbf{v}_p), \quad \Lambda = \text{diag}(\lambda_1, \dots, \lambda_p)$$

\mathbf{V} are known as the **loadings**

Interpretation in \mathbb{R}^p

\mathbf{V} describes a new orthogonal basis and a rotation of data in this basis

$$\left\{ \begin{array}{ccccccc} \Delta_1 & \oplus & \dots & \oplus & \Delta_p \\ \mathbf{v}_1 & \perp & \dots & \perp & \mathbf{v}_p \\ \lambda_1 & > & \dots & > & \lambda_p \\ I_{\Delta_1^\perp} & > & \dots & > & I_{\Delta_p^\perp} \end{array} \right.$$

∴ PCA is an appropriate rotation on axes that maximizes the variance

Unifying view of variables and individuals

In the new basis $\{\mathbf{v}_1, \dots, \mathbf{v}_p\}$, coordinates of i (a.k.a. **scores**) are

$$\mathbf{c}_i^\top = (\mathbf{x}_i - \bar{\mathbf{x}})^\top \mathbf{V} = \mathbf{X}_i^c \mathbf{V}, \quad \mathbf{c}_i \in \mathbb{R}^p.$$

In the variable space \mathbb{R}^n , new variables (factors) are formed by linear combinations of the original variables: the **principal components** (PC)

$$\mathbf{f}_k = \sum_{j=1}^p v_{kj} (\mathbf{x}^j - \bar{\mathbf{x}}_j) = \mathbf{X}^c \mathbf{v}_k, \quad \mathbf{f}_k \in \mathbb{R}^n$$

The matrix of PC connects individual coordinates to latent factors:

$$\text{PC} = \mathbf{X}^c \mathbf{V} = (\mathbf{f}_1 \quad \mathbf{f}_2 \quad \dots \quad \mathbf{f}_p) = \begin{pmatrix} \mathbf{c}_1^\top \\ \mathbf{c}_2^\top \\ \vdots \\ \mathbf{c}_n^\top \end{pmatrix}$$

↳ Everything can be interpreted on a single plot, called the biplot

Reconstruction formula

Recall that $\mathbf{F} = (\mathbf{f}_1, \dots, \mathbf{f}_p)$ is the matrix of Principal components. Then,

- $\mathbf{f}_k = \mathbf{X}^c \mathbf{v}_k$ for projection on axis k
- $\mathbf{F} = \mathbf{X}^c \mathbf{V}$ for all axis.

Using orthogonality of \mathbf{V} , we get back the original data as follows, without loss (\mathbf{V}^T performs the inverse rotation of \mathbf{V}):

$$\mathbf{X}^c = \mathbf{F} \mathbf{V}^T$$

We obtain an approximation $\hat{\mathbf{X}}^c$ (compression) of the data \mathbf{X}^c by considering a subset \mathcal{S} of PC, typically $\mathcal{S} = 1, \dots, q$ with $q \ll p$.

$$\hat{\mathbf{X}}^c = \mathbf{F}_q \mathbf{V}_q^T = \mathbf{X}^c \mathbf{V}_q \mathbf{V}_q^T$$

↔ This is a rank- q approximation of \mathbf{X} (captured by the first q axes).

Single-Cell data analysed with PCA

Toy single-cell RNA data set (https://github.com/LuyiTian/sc_mixology/)

The dataset scRNA contains the counts of the 500 most varying transcripts (tens of thousands) in the mixtures of 5 cell lines for a total of 3918 cells in human liver (obtained with standard 10x scRNaseq Chromium protocol).

Beyond PCA and linear methods

Limitations

Robust but,

- badly shaped for complex geometries (like multiscale properties)
- Fails with **Count** or **Skew** data (hidden Gaussian assumption)

Ideas

- Modify the model by playing with the **reconstruction error**
- Gain in versatility with **probabilistic/model-based approaches**
- Focus on **relationship preservation** to keep local characteristics
- Go **non-linear** by transforming the input space or amending the map
 $\Phi : \mathbb{R}^p \rightarrow \mathbb{R}^q$

Challenges

- tradeoff between interpretability and **versatility**
- tradeoff between **high** or low computational resource

Outline

- 1 Introduction
- 2 Background: Geometric view of PCA
- 3 Reconstruction error approach
- 4 Generative models
- 5 Preserving pairwise relations
- 6 Probabilistic Neighborhood Embedding

Reconstruction error approach: principle

Find maps Φ and $\tilde{\Phi}$ in a given family (e.g, linear, constraint on parameters, etc.), minimizing an error between \mathbf{x} and $\hat{\mathbf{x}} = \tilde{\Phi}(\Phi(\mathbf{x}))$

- **Distance** between \mathbf{X} and $\hat{\mathbf{X}}$, e.g, sum of squares:

$$\epsilon^{\text{SSQ}}(\mathbf{X}, \hat{\mathbf{X}}) = \|\mathbf{X} - \hat{\mathbf{X}}\|_F^2 = \sum_{i=1}^n \|\mathbf{x}_i - \tilde{\Phi}(\Phi(\mathbf{x}_i))\|^2$$

- **Divergence** between distributions $\hat{p}_{\mathbf{X}}$ and $\hat{p}_{\hat{\mathbf{X}}}$ of \mathbf{X}_i and $\hat{\mathbf{X}}_i$

$$D_{\text{KL}} (\hat{p}_{\mathbf{X}}, \hat{p}_{\hat{\mathbf{X}}}) = - \sum_i \hat{p}_{\mathbf{X}_i} \log \left(\frac{\hat{p}_{\mathbf{X}_i}}{\hat{p}_{\hat{\mathbf{X}}_i}} \right)$$

- **Log-likelihood** of a parametric model p_{θ} , with $\hat{\mathbf{X}} = f(\theta)$:

$$-\log p_{\theta}(\mathbf{X}) = - \sum_{i=1}^n \log p_{\theta}(\mathbf{X}_i)$$

Another interpretation of PCA

PCA model

Let \mathbf{V}_q be a $p \times q$ matrix whose columns are of q orthonormal vectors.

$$\Phi(\mathbf{x}) = \mathbf{V}_q^\top (\mathbf{x} - \boldsymbol{\mu}) = \mathbf{z}, \quad \hat{\mathbf{x}} = \tilde{\Phi}(\mathbf{z}) = \boldsymbol{\mu} + \mathbf{V}_q \mathbf{z}.$$

☞ Model with **Linear assumption + ortho-normality constraints**

PCA reconstruction error

$$\underset{\substack{\boldsymbol{\mu} \in \mathbb{R}^p \\ \mathbf{V}_q \in \mathcal{O}_{p,q}}}{\text{minimize}} \sum_{i=1}^n \|(\mathbf{x}_i - \boldsymbol{\mu}) - \mathbf{V}_q \mathbf{V}_q^\top (\mathbf{x}_i - \boldsymbol{\mu})\|^2 = \left(\underset{\substack{\mathbf{F}_q \in \mathcal{M}_{n,q} \\ \mathbf{V}_q \in \mathcal{O}_{p,q}}}{\text{minimize}} \|\mathbf{X}^c - \mathbf{F}_q \mathbf{V}_q^\top\|_F^2 \right)$$

Solution (explicit)

- $\boldsymbol{\mu}$ is the empirical mean, \mathbf{V}_q eigenvectors of the empirical covariance
- In practice: SVD of the centered matrix $\mathbf{X}^c = \mathbf{U}_q \mathbf{D}_q \mathbf{V}_q^\top = \mathbf{F}_q \mathbf{V}_q^\top$

Non-negative Matrix Factorization (Sra and Dhillon 2005)

Assume that \mathbf{X} contains only non-negative entries (i.e. ≥ 0).

Model: Linearity of Φ plus non-negativity constraints:

$$\hat{\mathbf{X}} \approx \underbrace{\mathbf{F}_q}_{\mathbf{F}_q} \mathbf{V}_q^\top, \text{ s.c. } \mathbf{F}_q, \mathbf{V}_q \text{ has non-negative entries.}$$

- Least-squares loss:

$$\hat{\mathbf{X}}^{\text{ls}} = \underset{\begin{subarray}{c} \mathbf{F} \in \mathcal{M}(\mathbb{R}_+)^{n,q} \\ \mathbf{V} \in \mathcal{M}(\mathbb{R}_+)^{p,q} \end{subarray}}{\arg \min} \|\mathbf{X} - \mathbf{F}\mathbf{V}^\top\|_F^2,$$

- Poisson likelihood for \mathbf{X}_{ij} with intensity $\lambda_{ij}^q = (\mathbf{F}_q \mathbf{V}_q^\top)_{ij} \geq 0$:

$$\hat{\mathbf{X}}^{\text{poisson}} = \underset{\begin{subarray}{c} \mathbf{F} \in \mathcal{M}(\mathbb{R}_+)^{n,q} \\ \mathbf{V} \in \mathcal{M}(\mathbb{R}_+)^{p,q} \end{subarray}}{\arg \max} \sum_{i,j} x_{ij} \log(\lambda_{ij}^q) - \lambda_{ij}^q.$$

Kernel-PCA (Schölkopf, Smola, and Müller 1998)

Principle: non linear transformation of \mathbf{x} prior to linear PCA

- ① Project the data into a higher space where it is linearly separable
- ② Apply PCA to the transformed data

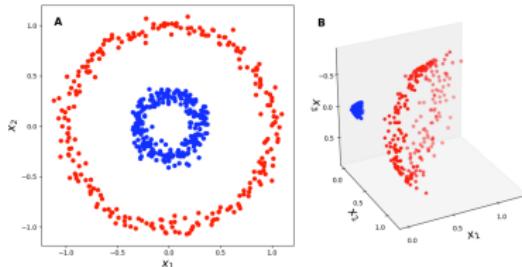

Figure 6: Transformation $\Psi : \mathbf{x} \rightarrow \Psi(\mathbf{x})$ (illustration in presence of existing labels)

Model

Assume a non linear transformation $\Psi(\mathbf{x}_i)$ where $\Psi : \mathbb{R}^p \rightarrow \mathbb{R}^n$, then perform PCA, with \mathbf{V}_q a $n \times q$ orthonormal matrix

$$\Phi(\mathbf{x}) = \mathbf{V}_q^\top \Psi(\mathbf{x} - \mu) = \mathbf{z}$$

Choice of the transformation

All relationships are described in terms of scalar products between $(\mathbf{x}_i, \mathbf{x}_{i'})$:

$$K = k(\mathbf{x}_1, \mathbf{x}_2) = (\Psi(\mathbf{x})_i, \Psi(\mathbf{x})_{i'}) = \Psi(\mathbf{x}_i)^\top \Psi(\mathbf{x}_{i'}),$$

where the kernel K is a symmetric positive definite function.

Some common kernels

Polynomial: $k(\mathbf{x}_i, \mathbf{x}_{i'}) = (\mathbf{x}_i^\top \mathbf{x}_{i'} + c)^d$

Gaussian: $k(\mathbf{x}_i, \mathbf{x}_{i'}) = \exp \frac{-\|\mathbf{x}_i - \mathbf{x}_{i'}\|^2}{2\sigma^2}$

Laplacian kernel: $k(\mathbf{x}_i, \mathbf{x}_{i'}) = \exp \frac{-\|\mathbf{x}_i - \mathbf{x}_{i'}\|}{\sigma}$

Kernel PCA suffers from the choice of the Kernel

Other methods

Linear models with other constraints

Let \mathbf{V}_q be a $p \times q$ matrix and $\mathbf{z} \in \mathbb{R}^q$

$$\hat{\mathbf{x}} = \tilde{\Phi}(\mathbf{z}) = \boldsymbol{\mu} + \sum_{j=1}^q \tilde{z}^j \mathbf{V}^j = \boldsymbol{\mu} + \mathbf{V}_q \mathbf{z}$$

Apply other constraints on \mathbf{V} and/or the factor/representation \mathbf{z}

- \mathbf{V}_q sparse, possibly orthogonal: **sparse PCA**
 - \mathbf{z} sparse : **Dictionary learning**
 - $(z^j, z^{j'})$ independent : **Independent Component Analysis**
- optimize square-loss $\|\mathbf{X} - \hat{\mathbf{X}}\|_F^2$ to fit $\boldsymbol{\mu}, \mathbf{V}, \mathbf{z}$

Outline

- 1 Introduction
- 2 Background: Geometric view of PCA
- 3 Reconstruction error approach
- 4 Generative models
- 5 Preserving pairwise relations
- 6 Probabilistic Neighborhood Embedding

Probabilistic Gaussian PCA (Tipping and Bishop 1999)

Generative model

pPCA is a special factor model with parameter $\theta = (\mathbf{C}, \sigma)$:

$$\begin{array}{lll} \text{latent space} & \mathbf{Z}_i & \text{i.i.d.} \quad \mathbf{W}_i \sim \mathcal{N}(\mathbf{0}_q, \mathbf{I}_q) \\ \text{observation space} & \mathbf{X}_i | \mathbf{Z}_i & \text{indep.} \quad \mathbf{X} | \mathbf{Z}_i \sim \mathcal{N}(\boldsymbol{\mu} + \mathbf{C}\mathbf{Z}, \sigma^2 \mathbf{I}_n) \end{array}$$

By direct integration², the marginal distribution of the observation is

$$p_{\theta}(\mathbf{X}_i) = \int_{\mathbb{R}^q} p_{\theta}(\mathbf{X}_i | \mathbf{Z}_i) p(\mathbf{Z}_i) d\mathbf{Z}_i = \mathcal{N}(\boldsymbol{\mu}, \Sigma), \quad \Sigma = \mathbf{C}\mathbf{C}^T + \sigma^2 \mathbf{I}_n$$

☞ rank- q decomposition of the covariance matrix + noise.

²easy since everything is Gaussian

Estimation

Criterion: negative log-likelihood

$$-\sum_{i=1}^n \log p_\theta(\mathbf{X}_i) = \log |\Sigma| + \text{tr}(\Sigma^{-1} \hat{\Sigma}), \quad \hat{\Sigma} = \frac{1}{n} \sum_i (\mathbf{x}_i - \bar{\mathbf{x}})(\mathbf{x}_i - \bar{\mathbf{x}})^\top$$

Maximum likelihood estimator

$$\hat{\mathbf{C}}^{\text{mle}} = \mathbf{V}_q (\Lambda_q - \hat{\sigma}^2 \mathbf{I}_n)^{1/2}, \quad \hat{\sigma}^2 = \frac{1}{p-q} \sum_{i=q+1}^p \lambda_i, \quad \hat{\Sigma} = \mathbf{V} \Lambda \mathbf{V}^\top$$

Latent position: posterior distribution

$$\mathbf{Z}_i | \mathbf{X}_i \sim \mathcal{N}(\mathbf{S}^{-1} \hat{\mathbf{C}}^\top (\mathbf{X}_i - \bar{\mathbf{x}}), \mathbf{S}^{-1} \hat{\sigma}^2), \quad \mathbf{S} = (\hat{\mathbf{C}}^\top \hat{\mathbf{C}} + \hat{\sigma}^2)$$

When $\sigma^2 \rightarrow 0$, $\mathbb{E}(\mathbf{Z}_i | \mathbf{X}_i) \equiv \text{orthogonal projection in the latent space.}$

Estimation: alternative

Expectation-Maximization

With $\mathcal{H}(p) = -\mathbb{E}_p(\log(p))$ the entropy of p , decompose

$$\log p_\theta(\mathbf{X}) = \mathbb{E}[\log p_\theta(\mathbf{X}, \mathbf{Z}) | \mathbf{X}; \theta] + \mathcal{H}[p_\theta(\mathbf{Z} | \mathbf{X}; \theta)]$$

EM requires to evaluate (some moments of) $p_\theta(\mathbf{Z} | \mathbf{X}; \theta)$

- E-step: evaluate $Q(\theta | \theta') = \mathbb{E}(\log \ell(\mathbf{X}, \mathbf{W}; \theta) | \mathbf{X}; \theta')$
- M-step: update θ by maximizing $Q(\theta | \theta')$

EM for pPCA

- E-step: update the latente position means $\mathbb{E}(\mathbf{Z} | \mathbf{X})$
- M-step: update the model parameters \mathbf{C}, σ^2

→ can be faster than MLE when $p \gg q$

PCA for counts: poisson lognormal PCA

Generative Model (Chiquet, Mariadassou, and Robin 2018)

$$\begin{array}{lll} \text{latent space} & \mathbf{Z}_i & \text{i.i.d.} \\ \text{observation space} & \mathbf{X}_i | \mathbf{Z}_i & \text{indep.} \end{array} \quad \begin{aligned} \mathbf{Z}_i &\sim \mathcal{N}(\mathbf{0}_q, \mathbf{I}_q) \\ \mathbf{X}| \mathbf{Z}_i &\sim \mathcal{P}\left(\exp\{\boldsymbol{\mu} + \mathbf{C}^\top \mathbf{Z}_i\}\right) \end{aligned}$$

Estimation: Issues

- The marginal distribution is hard to compute, even numerically

$$p_{\theta}(\mathbf{X}_i) = \int_{\mathbb{R}_p} \prod_{j=1}^p p_{\theta}(X_{ij}|Z_{ij}) p_{\theta}(\mathbf{Z}_i) d\mathbf{Z}_i$$

↗ no direct MLE possible

- Posterior distribution of \mathbf{Z}_i has no close form

↗ no genuine application of EM possible

Variational inference (Chiquet, Mariadassou, and Robin 2021)

Variational approximation Blei, Kucukelbir, and McAuliffe (2017)

- Use a proxy q_ψ of $p_\theta(\mathbf{Z} | \mathbf{X})$ minimizing a divergence in a class \mathcal{Q}

$$q_\psi(\mathbf{Z})^* = \arg \min_{q \in \mathcal{Q}} KL(q(\mathbf{Z}), p(\mathbf{Z}|\mathbf{Y})), \quad KL(., .) = \mathbb{E}_{q_\psi} \left[\log \frac{q(z)}{p(z)} \right].$$

- maximize the ELBO (Evidence Lower BOund)

$$J(\theta, \psi) = \log p_\theta(\mathbf{Y}) - KL[q_\psi(\mathbf{Z}) \| p_\theta(\mathbf{Z}|\mathbf{Y})] = \mathbb{E}_\psi [\log p_\theta(\mathbf{Y}, \mathbf{Z})] + \mathcal{H}[q_\psi(\mathbf{Z})]$$

Variational EM for Poisson-lognormal

Consider \mathcal{Q} the class of diagonal multivariate Gaussian distributions.

The ELBO $J(\theta, \psi)$ has close-form and is bi-concave.

- E-step: solve in ψ for given θ
- M-step: solve in θ for given ψ

Model selection and Visualization for PLN-PCA

Selection of number of components (rank k)

Use likelihood lower bound in information criteria, e.g,

$$\hat{k} = \arg \max_k \text{vBIC}_k \quad \text{with } \text{vBIC}_k = J(\hat{\beta}, \tilde{p}) - \frac{1}{2} p(d+k) \log(n)$$

Visualization: non-nested subspaces (\neq Gaussian PCA)

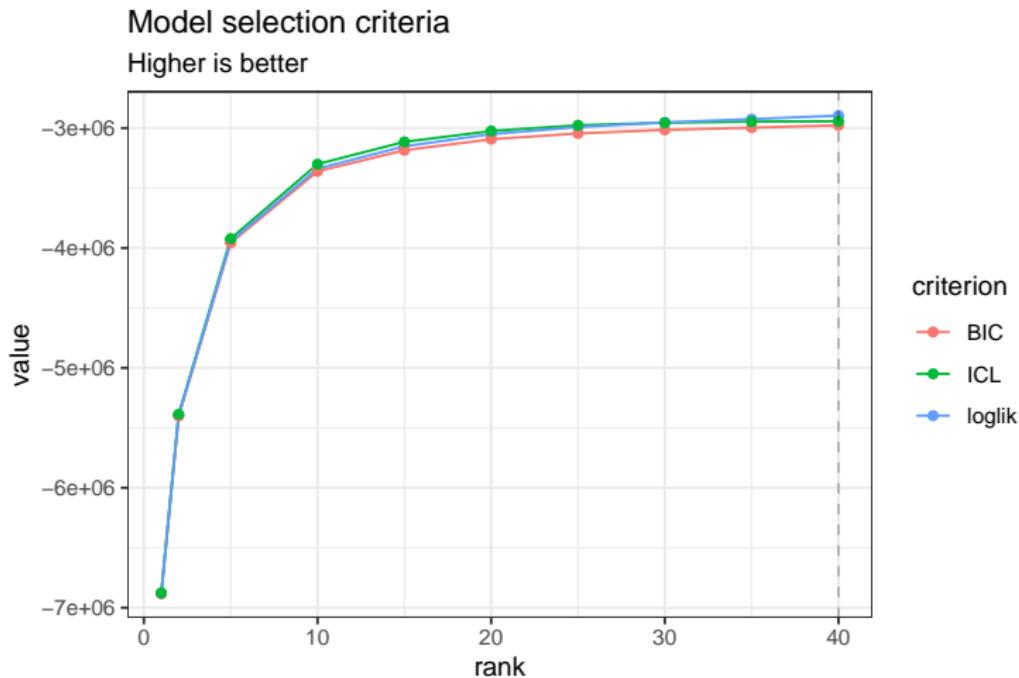

For the selected dimension \hat{k} , compute the estimated latent positions $\mathbb{E}_q(\mathbf{Z}_i)$ and perform PCA

Goodness of fit: deviance based criterion

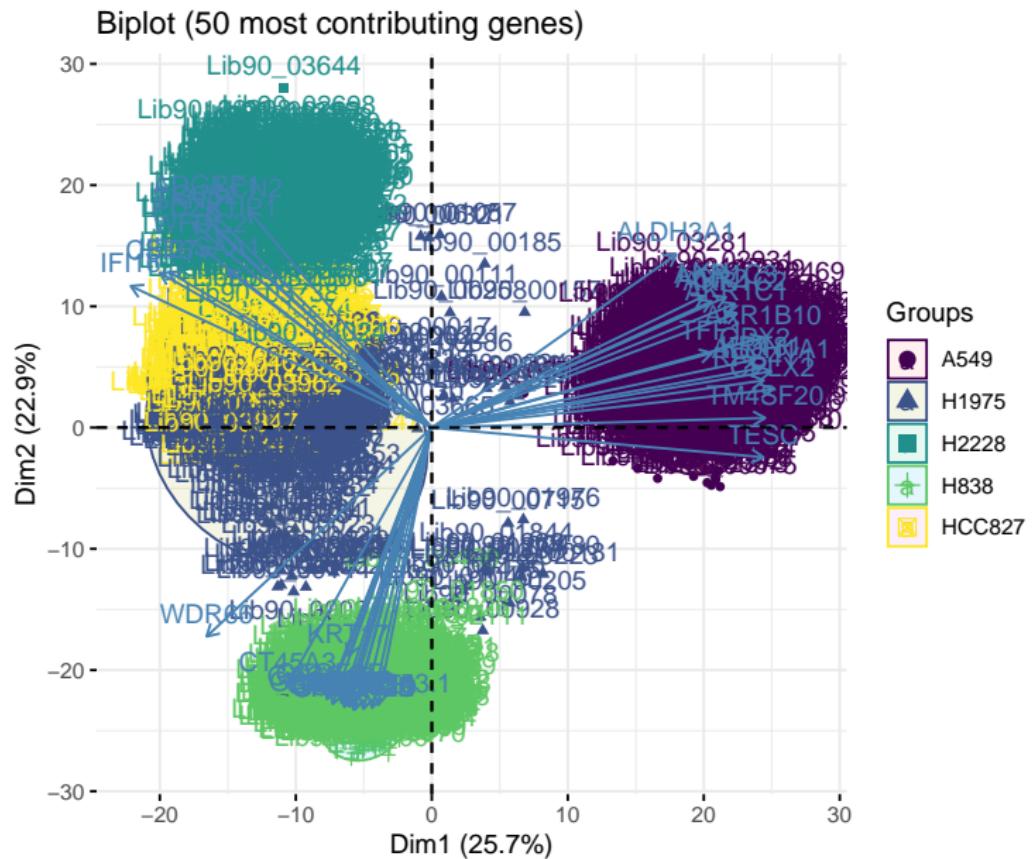

For $\ell_k = \log \mathbb{P}(\mathbf{X}; \lambda^{(k)})$ the Poisson likelihood,

$$R_k^2 = \frac{\ell_k - \ell_0}{\ell_{\max} - \ell_0}, \quad \text{with } \lambda_{ij}^{(k)} = \exp\left(\mathbb{E}_q(Z_{ij}^{(k)})\right), \quad \lambda_{ij}^{\max} = Y_{ij}.$$

Poisson-lognormal PCA for the scRNA data set

Poisson-lognormal PCA for the scRNA data set

Variational Auto-Encoders (Kingma and Welling 2013)

Highly non-linear model

Find Φ and $\tilde{\Phi}$ with **two** neural-networks, controlling the error.

$$\epsilon(\mathbf{X}, \hat{\mathbf{X}}) = \sum_{i=1}^n \|\mathbf{x}_i - \tilde{\Phi}(\Phi(\mathbf{x}_i))\|^2 + \text{regularization}(\Phi, \tilde{\Phi})$$

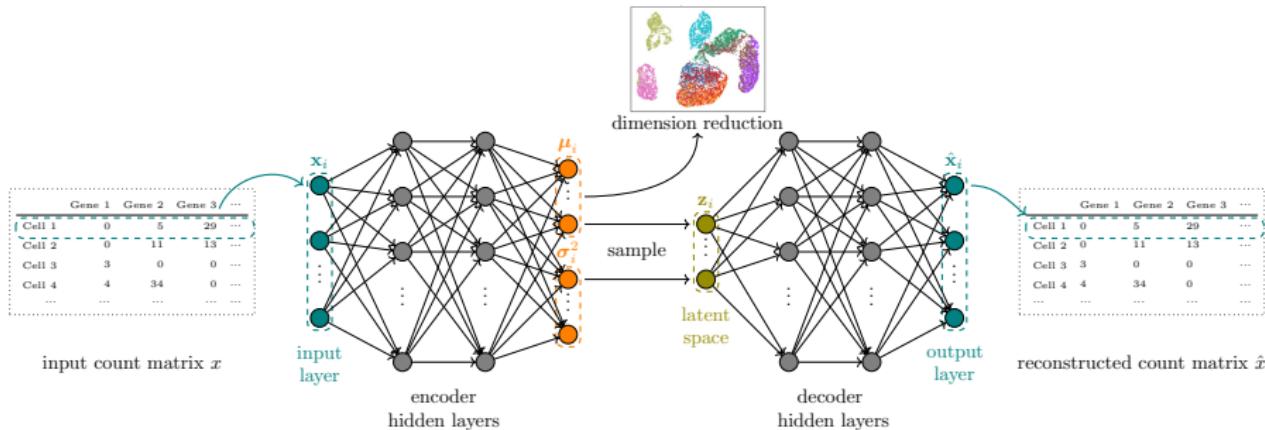

Figure 13: Figure by Hugo Gangloff

Variational Auto-Encoders

Decoder: Generative model

$$p_{\theta}(\mathbf{X}_i, \mathbf{Z}_i) = p_{\theta}(\mathbf{Z}_i)p_{\theta}(\mathbf{X}_i|\mathbf{Z}_i), \text{ with } \begin{cases} p_{\theta}(\mathbf{Z}_i) &= \mathcal{N}(0, \mathbf{I}_q), \\ p_{\theta}(\mathbf{X}_i|\mathbf{Z}_i) &\text{cond. likelihood.} \end{cases}$$

Encoder: Variational Inference model

The encoder approximate the posterior distribution with $q_{\psi}, \psi = \{\boldsymbol{\mu}_i, \boldsymbol{\sigma}^2\}$:

$$q_{\psi}(\mathbf{Z}_i|\mathbf{X}_i) = \mathcal{N}(\boldsymbol{\mu}_i, \boldsymbol{\sigma}_i^2 \mathbf{I}_q) \approx p_{\theta}(\mathbf{Z}_i|\mathbf{X}_i)$$

Optimization/training

Maximize a lower bound of the marginal log $p_{\theta}(\mathbf{X})$ (a.k.a the ELBO):

$$\log p_{\theta}(\mathbf{X}_i) \geq \mathcal{E}_{\theta, \psi}(\mathbf{X}_i) = \mathbb{E}_{q_{\psi}(\mathbf{Z}_i|\mathbf{X}_i)} [\log p_{\theta}(\mathbf{X}_i|\mathbf{Z}_i)] - D_{KL}(q_{\psi}(\mathbf{Z}_i|\mathbf{X}_i) \| p_{\theta}(\mathbf{Z}_i))$$

Variational Auto-Encoders

Likelihoods relevant for count data

- Data scaled to $[0,1]$ + Continuous Bernoulli (CB) likelihood (Wang and Gu 2018)
- (Zero Inflated) Negative Binomial (ZINB) likelihood (Dony et al. 2020)
- **(Zero Inflated) Poisson likelihood** (tried this with Hugo Gangloff)

Let $\lambda \in (\mathbb{R}_*)^p$ and $\rho \in [0, 1]^p$ be the outputs of the decoder,

$$p_{\theta}(\mathbf{x}|\mathbf{z}) = \prod_{j=1}^p \begin{cases} \rho_j + (1 - \rho_j)p_{\theta}^{Poiss}(x_{m,n}|\lambda_n), & x_{ij} = 0, \\ (1 - \rho_j)p_{\theta}^{Poiss}(x_{ij}|\lambda_n), & x_{ij} > 0. \end{cases}$$

Outline

- 1 Introduction
- 2 Background: Geometric view of PCA
- 3 Reconstruction error approach
- 4 Generative models
- 5 Preserving pairwise relations
- 6 Probabilistic Neighborhood Embedding

Preserving pairwise relations: principle

Consider an $n \times n$ (dis)similarity matrix associated to $\mathbf{x}_i \in \mathbb{R}^p$, measuring pairwise relations $\mathcal{R}(\bullet, \bullet')$, using one among

- distances,
- kernels,
- inner products,
- probability distributions.

Goal: find $\mathbf{z}_i \in \mathbb{R}^q$ while preserving the (dis)similarities in the latent space

Preserve local properties

Find a map Φ from $\mathbb{R}^p \rightarrow \mathbb{R}^q$ such that

$$\mathcal{R}(\mathbf{x}_i, \mathbf{x}_{i'}) \sim \mathcal{R}'(\mathbf{z}_i, \mathbf{z}_{i'})$$

→ preserve \mathcal{R} both in high and low dimensional spaces to catch complex geometries

Multidimensional scaling

a.k.a Principale Coordinates Analysis

Classical Multidimensional Scalings

Preserve similarities in terms **inner product**:

$$\text{Stress}^{cMDS}(\mathbf{z}_i) = \sum_{i \neq i'} \left((\mathbf{x}_i - \boldsymbol{\mu})^\top (\mathbf{x}_i - \boldsymbol{\mu}) - \mathbf{z}_i^\top \mathbf{z}_{i'} \right)^2,$$

Metric Multidimensional Scalings

Remark that cMDS amount to preserve dissimilarities in terms of Euclidean distance, use

$$\text{Stress}(\mathbf{z}_1, \dots, \mathbf{z}_n) = \sum_{i \neq i'} (d_{ii'} - \|\mathbf{z}_i - \mathbf{z}_{i'}\|)^2,$$

☞ Generalize to other dissimilarities/distances or stress functions

Some Embedding methods

Isomap (Balasubramanian and Schwartz 2002)

- Build a k -nearest neighbor graph with adjacency matrix \mathbf{W}
- Weight edges by $W_{ii'} = \|\mathbf{x}_i - \mathbf{x}_{i'}\|$
- Compute the shortest path distance
- Embeds the distance with MDS.

Laplacian Eigenmaps (Belkin and Niyogi 2003)

- Build a k -nearest neighbor graph with adjacency matrix \mathbf{W}
- Weight edges with Gaussian kernel $W_{ii'} = \exp(-\|\mathbf{x}_i - \mathbf{x}_{i'}\|^2/\sigma^2)$
- Compute the graph Laplacian $\mathbf{L} = \mathbf{D} - \mathbf{W}$ with \mathbf{D} diagonal with degrees
- Embeddings are obtained with the first eigenvectors associated to positive eigenvalues of \mathbf{L} .

Classical embeddings on scRNA data set⁵

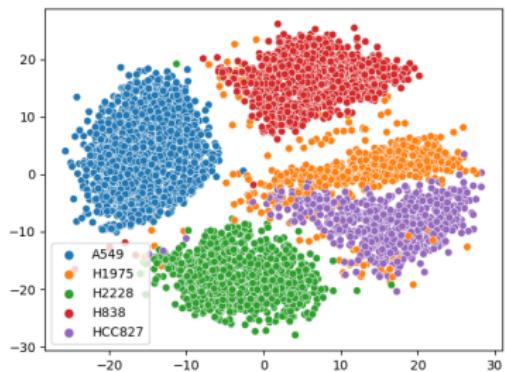

Figure 18: Multidimensional Scaling

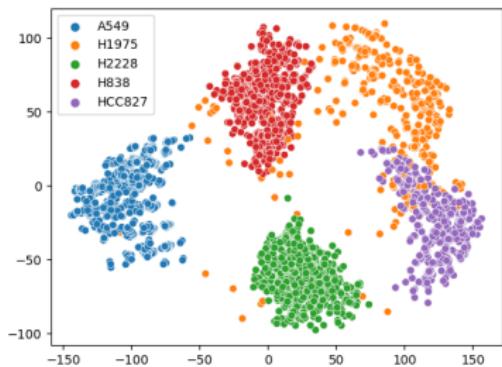

Figure 19: Isomap

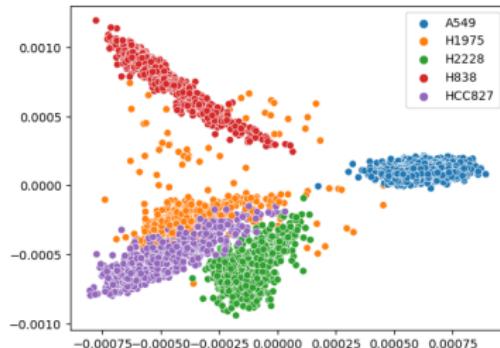

Figure 20: Laplacian Eigenmap

Stochastic Neighbor Embedding (SNE) (Hinton and Roweis 2002)

High dimensional space

Let $(\mathbf{x}_1, \dots, \mathbf{x}_n)$ be the original points in \mathbb{R}^p , and measure similarities by

$$p_{ij} = (p_{j|i} + p_{i|j})/2n, \quad \text{with } p_{j|i} = \frac{\exp(-\|\mathbf{x}_j - \mathbf{x}_i\|^2/2\sigma_i^2)}{\sum_{k \neq i} \exp(-\|\mathbf{x}_k - \mathbf{x}_i\|^2/2\sigma_i^2)}$$

- preserves relations with **close neighbors**
- σ_i adjusts to local densities (neighborhood of i)

Perplexity

A smoothed effective number of neighbors:

$$Perp(p_i) = 2^{H(p_i)}, \quad H(p_i) = - \sum_{j=1}^n p_{j|i} \log_2 p_{j|i}$$

→ σ_i found by binary search to match a user-defined perplexity for p_i

tSNE and Student / Cauchy kernels (Maaten and Hinton 2008)

Similarities in the low dimension space

Let $(\mathbf{z}_1, \dots, \mathbf{z}_n)$ be the points in the the low-dimensional space $\mathbb{R}^{q=2}$

$$(\text{SNE}) \quad q_{i|j} = \frac{\exp(-\|\mathbf{z}_i - \mathbf{z}_j\|^2)}{\sum_{k \neq i} \exp(-\|\mathbf{z}_k - \mathbf{z}_j\|^2)}$$

$$(\text{t-SNE}) \quad q_{i|j} = \frac{(1 + \|\mathbf{z}_i - \mathbf{z}_j\|^2)^{-1}}{\sum_{k \neq i} (1 + \|\mathbf{z}_i - \mathbf{z}_k\|^2)^{-1}}$$

☞ t-SNE robustifies Gaussian kernel by using Student(1) (Cauchy) kernels

Optimization

Criterion – Kullback-Leibler between p and q : $C(\mathbf{z}) = \sum_{ij} KL(p_{ij}, q_{ij})$

Algorithm – adaptive stochastic gradient initialized by $\mathcal{N}(0, \epsilon I_q)$

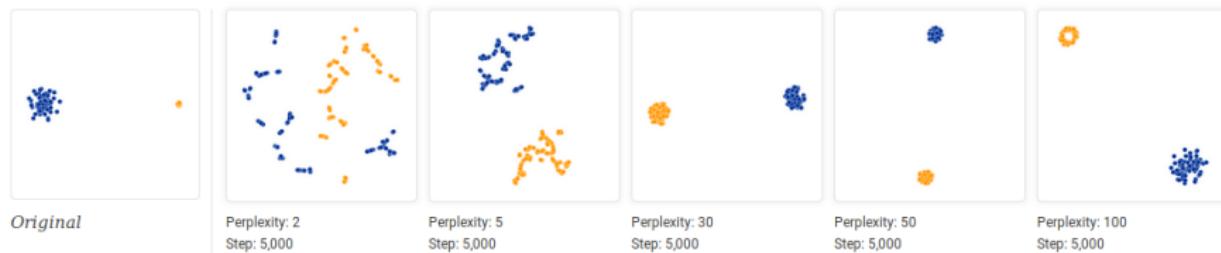

Initialization – reduce original data with PCA then initialized by $\mathcal{N}(0, \epsilon I_q)$

Empirical properties of tSNE (1)

Effect of Hyperparameters : Perplexity

tSNE does not account for heteroscedasticity

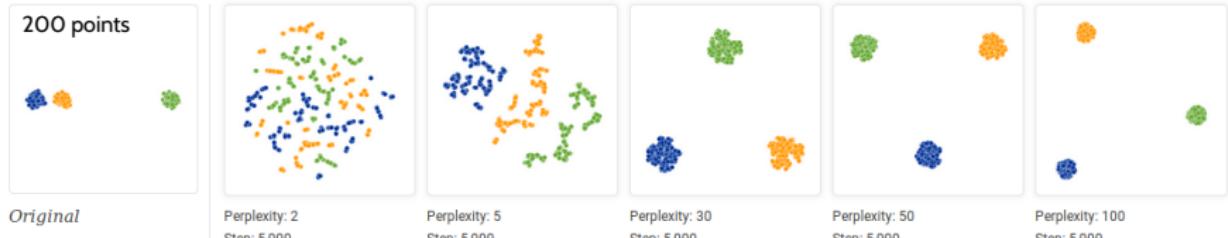

Empirical properties of tSNE (2)

tSNE does not account for between-cluster distance

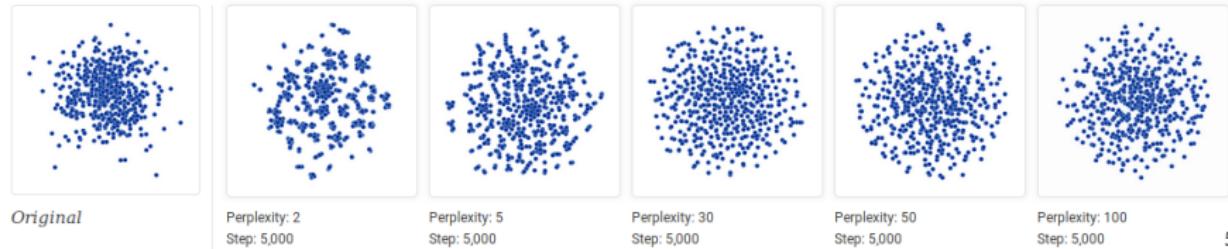

50 points

200 points

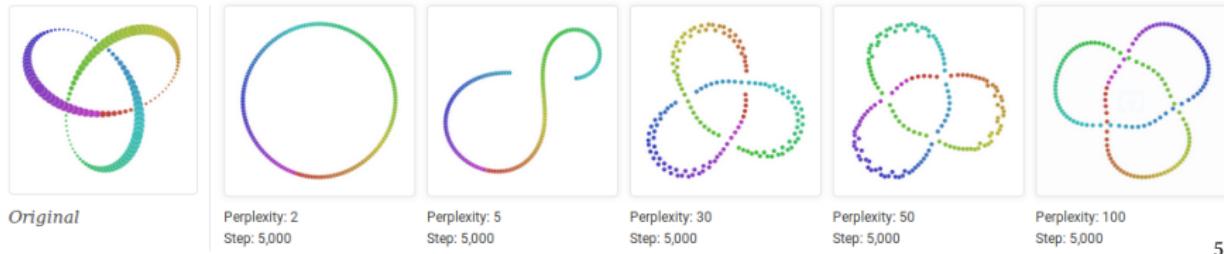

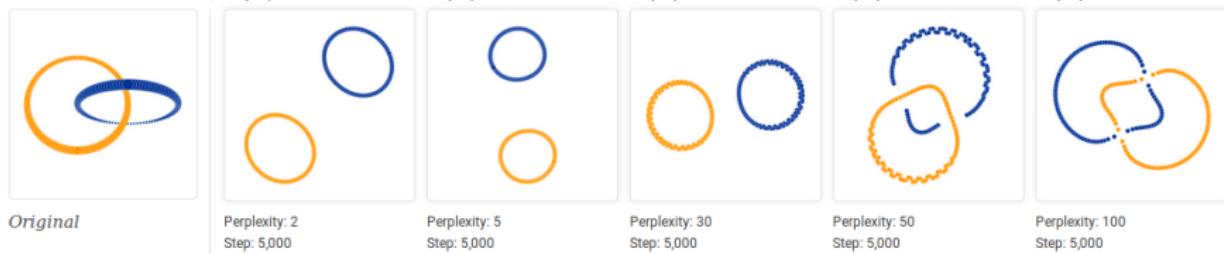

What about random noise ?

Empirical properties of tSNE (3)

Catching Complex Geometries

t-SNE: pros/cons

Properties

- good at preserving local distances (intra-cluster variance)
- not so good for global representation (inter-cluster variance)
- good at creating clusters of close points, bad at positioning clusters wrt each other

Limitations

- importance of preprocessing: initialize with PCA and feature selection plus log transform (non linear transform)
- percent of explained variance ? interpretation of the q distribution ?
- Lack of reproducibility due to stochastic optimization

Uniform Manifold Approximation and Projection

McInnes, Healy, and Melville (2018)

For j in the k -neighborhood of i , define the conditional distribution

$$p_{j|i} = \exp\left(-\frac{\|X_i - X_j\|_2^2 - \rho_i}{\sigma_i}\right) \quad \text{with } \rho_i = \min_{j \neq i} \|X_i - X_j\|^2$$

and its symmetrized version

$$p_{ij} = p_{j|i} + p_{i|j} - p_{j|i}p_{i|j}.$$

Rely on a generalized Student-distribution with a, b fitted on the data:

$$q_{ij} = \left(1 + a\|Z_i - Z_j\|_2^{2b}\right)^{-1}$$

UMAP solves the following problem:

$$\min_{Z \in \mathbb{R}^{n \times d}} - \sum_{i < j} p_{ij} \log q_{ij} + (1 - p_{ij}) \log(1 - q_{ij})$$

- 3 Reconstruction error approach
- 4 Generative models
- 5 Preserving pairwise relations
- 6 Probabilistic Neighborhood Embedding

Hidden Graph to structure observations

Consider W the adjacency matrix of a hidden random graph⁸

The graph Laplacian operator is the map L such that

$$L(\mathbf{W})_{ij} = \begin{cases} -W_{ij} & \text{if } i \neq j \\ \sum_{k \in [n]} W_{ik} & \text{otherwise.} \end{cases}$$

$L = L(\mathbf{W})$ has the following property:

$$\forall X \in \mathbb{R}^{n \times p}, \quad \sum_{i,j} W_{ij} \|X_i - X_j\|^2 = \text{tr}(X^T L X).$$

⁸we start with one connected component

Conditional distribution of X on a graph W_X

Consider a Matrix Normal model with row and column dependencies

$$X | W_X \sim \mathcal{MN}\left(0, L_X^{-1}, \Sigma^{-1}\right),$$

The conditional density relates to the Gaussian kernel

$$k(X_i - X_j) = \exp\left(-\frac{1}{2}\|X_i - X_j\|_{\Sigma}^2\right),$$

which can be generalized to translation invariant kernels:

$$\mathbb{P}(X | W_X) \propto \prod_{(i,j) \in [n]^2} k(\mathbf{X}_i - \mathbf{X}_j)^{W_{X,ij}}.$$

Conditional distribution of Z on a graph W_Z

Consider that the low-dimensional representation is also structured according to a graph

$$Z | W_Z \sim \mathcal{MN}\left(0, L_Z^{-1}, I_q\right),$$

with the Gaussian kernel for Z

$$k(Z_i - Z_j) = \exp\left(-\frac{1}{2}\|Z_i - Z_j\|_{I_q}^2\right),$$

The Conditional distribution of $Z | W_Z$ is

$$\mathbb{P}(Z | W_Z) \propto \prod_{(i,j) \in [n]^2} k(Z_i - Z_j)^{W_{Z,ij}}$$

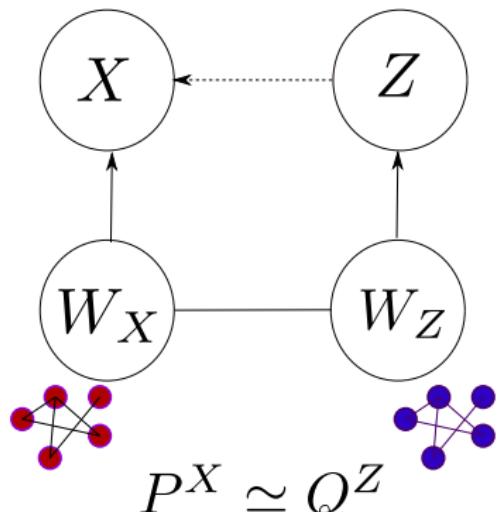

Embedding with Graph Coupling

Couple the 2 hidden graphs W_X and W_Z in a probabilistic way by matching their posterior distributions:

$$P^X = \mathbb{P}(W_X | X)$$

$$Q^Z = \mathbb{P}(W_Z | X; Z)$$

⤱ Z becomes a parameter to be estimated

Probabilistic Coupling

Graph Coupling with Z as a parameter

Consider the cross entropy between posteriors

$$\mathcal{H}(\mathbf{P}^X, \mathbf{Q}^Z) = -\mathbb{E}_{W_X \sim \mathbf{P}^X} \left(\log \mathbb{P}(W_Z = W_X \mid X; Z) \right)$$

Find the best low-dimensional representation such that the two graphs match

$$Z(X) = \arg \min_Z \left\{ \mathcal{H}(\mathbf{P}^X, \mathbf{Q}^Z) \right\}$$

Connection with the KL between posteriors

$$\text{KL}(\mathbf{P}^X, \mathbf{Q}^Z) = \mathcal{H}(\mathbf{P}^X, \mathbf{Q}^Z) - \mathcal{H}(\mathbf{P}^X, \mathbf{P}^X)$$

Conjugate priors and posteriors for hidden graphs

Consider a prior distribution for the hidden graph in the general form

$$\mathbb{P}_{\mathcal{P}}(\mathbf{W}; \boldsymbol{\pi}) \propto \underbrace{\mathcal{C}_k(W)^\alpha}_{\alpha=0} \Omega_{\mathcal{P}}(\mathbf{W}) \prod_{(i,j) \in [n]^2} \pi_{ij}^{W_{ij}}$$

For the following priors family, we derive the posterior $\mathbb{P}_{\mathcal{P}}(\mathbf{W} \mid X; \boldsymbol{\pi}, k)$

\mathcal{P}	$\Omega_{\mathcal{P}}(\mathbf{W})$	Prior for W
\mathcal{B} Bernoulli	$\prod_{ij} \mathbf{1}_{W_{ij} \leq 1}$	$\mathcal{B}\left(\frac{\pi_{ij}}{1+\pi_{ij}}\right)$
\mathcal{D} Unitary Fixed degree	$\prod_i \mathbf{1}_{W_{i+} = 1}$	$\mathcal{M}\left(1, \frac{\boldsymbol{\pi}_i}{\pi_{i+}}\right)$
\mathcal{E} Fixed Number of edges	$\prod_{ij} (W_{ij}!)^{-1}$	$\mathcal{M}\left(n, \frac{\boldsymbol{\pi}}{\pi_{++}}\right)$

$\pi_{ij}k_{ij} = \pi_{ij}k(X_i - X_j)$ is the posterior strength of edges (normalized or not)

Mixing Prior distributions for coupling

Priors for W_X, W_Z induce posteriors $\mathbf{P}^{\mathcal{P}_X}, \mathbf{Q}^{\mathcal{P}_Z}$ matched with cross entropy $\mathcal{H}(\mathbf{P}^{\mathcal{P}_X}, \mathbf{Q}^{\mathcal{P}_Z})$

Model-based Neighbor Embedding

Choosing $\mathcal{P}_X = \mathcal{P}_Z = \mathcal{D}$ lead us to $\mathcal{H}_{D,D} = - \sum_{i \neq j} P_{ij}^D \log Q_{ij}^D$ and

$$P_{ij}^D = \frac{\pi_{ij} k(X_i - X_j)}{\sum_{\ell=1}^n \pi_{i\ell} k(X_i - X_\ell)}, \quad Q_{ij}^D = \frac{\pi_{ij} k(Z_i - Z_j)}{\sum_{\ell=1}^n \pi_{i\ell} k(Z_i - Z_\ell)}.$$

We defined the generative model for SNE!. Similarly,

Algorithm	Input Similarity	Latent Similarity	Loss Function
SNE	$P_{ij}^D = \frac{k_x(\mathbf{x}_i - \mathbf{x}_j)}{\sum_{\ell} k_x(\mathbf{x}_i - \mathbf{x}_{\ell})}$	$Q_{ij}^D = \frac{k_z(\mathbf{z}_i - \mathbf{z}_j)}{\sum_{\ell} k_z(\mathbf{z}_i - \mathbf{z}_{\ell})}$	$-\sum_{i \neq j} P_{ij}^D \log Q_{ij}^D$
Sym-SNE	$\bar{P}_{ij}^D = P_{ij}^D + P_{ji}^D$	$Q_{ij}^E = \frac{k_z(\mathbf{z}_i - \mathbf{z}_j)}{\sum_{\ell} k_z(\mathbf{z}_i - \mathbf{z}_{\ell})}$	$-\sum_{i < j} \bar{P}_{ij}^D \log Q_{ij}^E$
LargeVis	$\bar{P}_{ij}^D = P_{ij}^D + P_{ji}^D$	$Q_{ij}^B = \frac{k_z(\mathbf{z}_i - \mathbf{z}_j)}{1 + k_z(\mathbf{z}_i - \mathbf{z}_j)}$	$-\sum_{i < j} \bar{P}_{ij}^D \log Q_{ij}^B + \left(2 - \bar{P}_{ij}^D\right) \log(1 - Q_{ij}^B)$
UMAP	$\widetilde{P}_{ij}^B = P_{ij}^B + P_{ji}^B - P_{ij}^B P_{ji}^B$	$Q_{ij}^B = \frac{k_z(\mathbf{z}_i - \mathbf{z}_j)}{1 + k_z(\mathbf{z}_i - \mathbf{z}_j)}$	$-\sum_{i < j} \widetilde{P}_{ij}^B \log Q_{ij}^B + \left(1 - \widetilde{P}_{ij}^B\right) \log(1 - Q_{ij}^B)$
